

PROBLEM STATEMENT

AI Assistant for Government Scheme Discovery

A Flutter-based conversational assistant to help citizens find schemes they qualify for

Domain	Mobile App / Applied AI
--------	-------------------------

Objective

Build a proof-of-concept AI-powered Android application (Flutter) that helps Indian citizens discover government welfare schemes they may be eligible for, and clearly explains the associated benefits, in a natural, conversational way.

Scope of Work

The assistant should be able to:

- Understand free-form user queries about government schemes and benefits
- Ask clarifying follow-up questions to collect relevant eligibility details
- Identify and shortlist schemes the user is likely eligible for
- Clearly explain each scheme's benefits, eligibility criteria, and required documents
- Explain the application process and where to apply
- Support natural back-and-forth follow-up questions within the conversation

User Information Considered for Eligibility

To match the user with relevant schemes, the assistant may ask for and use details such as: state, district or city, age, gender, occupation, income bracket, education level, social category (where applicable to a scheme), disability status, farmer status, student status, and employment status. All such information should be collected transparently, used only for scheme matching, and never stored or shared beyond what is required for the POC demo.

AI & Data Requirements

- Natural language understanding of user queries and conversational context
- Ability to ask smart follow-up questions rather than requiring a rigid form
- Grounded responses - the assistant should answer based on verified scheme information, not fabricate details
- Clear handling of uncertainty (e.g., tell the user when it isn't sure, rather than guessing)
- Scheme information should be sourced only from authenticated, publicly available government sources (e.g., official scheme portals)

Suggested Technology Stack

- Frontend: Flutter (Android)
- Backend: Python (FastAPI)
- AI Layer: A capable large language model (e.g., GPT-5.x or an equivalent modern LLM), used with retrieval over verified scheme data
- Database: PostgreSQL
- Optional (for better accuracy): a Vector Database + Retrieval-Augmented Generation (RAG) pipeline over official scheme documents

Deliverables

- A working Flutter Android app
- Backend APIs powering the assistant
- AI/LLM integration with grounded, source-backed responses
- Architecture diagram
- Database schema
- Setup and deployment guide
- A recorded demo video showing a sample conversation and scheme recommendations

Expected Outcome

A working AI assistant proof-of-concept that has a natural conversation with a citizen, asks the right follow-up questions, and returns personalized, source-backed government scheme recommendations with clear eligibility and application guidance.

Note: Any personal information entered during the demo (income, category, etc.) should be treated as sensitive test data only - not stored beyond the POC, and never real personal data of any individual.
